The open source VPN client and server are free, modular software which support virtually any VPN technology. OpenVPN's client and server client designs are portable, and support embedded devices like PDAs and cell phones. OpenVPN uses the SSL/TLS protocol for security to provide an encrypted tunnel for your computer to connect to your network. OpenVPN is also a dynamic routing protocol for secure, peer-to-peer tunnels. OpenVPN is a fully managed solution for site-to-site and site-to-internet connections to secure remote locations. OpenVPN is a well-rounded and feature-rich solution that offers, at a low cost, a secure means of surfing the web. It can act as a server, client, or both. It has multiple modes of operations, allowing you to utilize OpenVPN for a wide range of purposes. OpenVPN Features: Dynamic Routing: OpenVPN is a dynamic routing protocol. This means that you can utilize it to form a VPN tunnel between two OpenVPN client machines which leads to a secure connection to a remote network. User-based Authentication: OpenVPN offers user-based authentication, which means that it can authenticate users based on username and/or password. This allows you to create a secure VPN tunnel to one or more computers, or it allows you to secure only certain remote computers on your network. Network Access Control: OpenVPN can be used to control access to and from the network. For example, you can limit the computers that a user can access the network from; this way, you can limit the time that a user can be on the network. SSL/TLS Encryption: The SSL/TLS protocol is used in OpenVPN. This protocol allows you to form a tunnel to a remote network and securely access it. Advanced Routing: OpenVPN supports several advanced routing techniques. For example, OpenVPN can form a virtual interface to a remote network and load balance traffic between the interfaces. Easy to Install: OpenVPN includes a command-line interface (CLI) as well as a web-based interface. Once you configure the CLI, you can quickly set up a VPN tunnel. OpenVPN's GUI does not force you to enter configuration information in a specific format. This makes it easier to set up the configuration. Single-Sign On: OpenVPN can allow you to use a single username and password to access the VPN tunnel. This makes it easier to control access.

OpenVPN is an open source VPN software designed to provide secure remote access to a private network, while offering VPN clients open access to the Internet. Most cheap VPN offerings cost as little as \$5 per month. OpenVPN on the other hand is priced between \$15 and \$40 per month (depending on the amount of bandwidth you require). OpenVPN is freely redistributable. Anyone can copy the OpenVPN source code and use it however they like (including to make and sell open source VPN software of their own). It is licensed under a BSD style license, and as such, you can use the OpenVPN software and make money on it by selling your own VPN software that is based on the OpenVPN source code. OpenVPN is secure. OpenVPN provides a strong and robust means of securing your data and connecting from the Internet. In fact, OpenVPN was developed using research conducted by the NSA (National Security Agency), which indicates the strong encryption used in OpenVPN is from the very best encryption algorithms currently available (including Triple DES, Blowfish, and many others). OpenVPN is easy to set up. Unlike other VPN protocols, OpenVPN is designed to be simple and intuitive to set up, making it suitable for any setup. OpenVPN is very easy to use. Using OpenVPN is easy and fast. You can configure OpenVPN in seconds using just a text file, with which you can easily set up a Virtual Private Network (VPN) service for remote access to your private network, or for securing your web surfing from the Internet. In fact, since OpenVPN is so easy to use, many of the administrators of large VPN networks are able to do it themselves, which gives you greater freedom and better security. OpenVPN can handle more than one VPN client, and can handle hundreds of VPN clients simultaneously. The number of simultaneous connections is limited only by the CPU speed and memory available. OpenVPN can be used with more than one 09e8f5149f

OpenVPN is a VPN implementation available under the open-source license. An OpenVPN client connection opens a virtual network tunnel over a single layer two (L2) or three (L3) secure connection. More specifically, OpenVPN operates over a TLS connection made to a server at any one of a possible number of locations. The tunnel that is established actually goes through any number of points of connection between the connection end points, including over the Internet where it appears as a physical point-to-point link. At any intermediate point, the tunnel is decrypted and the data is usually re-encrypted and returned to its original connection end point. The tunnel, including any data that has passed through the tunnel, then appears to the remote end point as if the data actually passed through the same intermediate point on its way to the remote end point. The security of the entire tunnel therefore depends on the security of the intermediate points and of the connections at those points, including the L3 protocol. OpenVPN is suited to a variety of network scenarios. OpenVPN has the advantage of a variety of client-side authentication methods, including certificates, T-Keys, or 2-factor authentication tokens, and the ability to use the OpenVPN client itself as an authentication mechanism for the server. It can also support remote authorization using RADIUS, NIS, LDAP, or other authentication protocols.

Server Authentication With OpenVPN When OpenVPN initially connected to a VPN server it attempts to find the main OpenVPN configuration file with the name `vpn_username@remotehost`. If it cannot find it, it will then create a new `vpn_username@remotehost` configuration file. If `vpn_username@remotehost` file does not exist, then OpenVPN will create a new file for that user, its default configuration is `vpn_username = vpn_password@host`. It will then ask the user for the Password. After the connection is made, the server is then ready to provision user's client access. Below is an OpenVPN configuration file for connecting to a server over port 443 using SSLv3. In this example the server is located at `thisserver.com`. In all configuration files, we use the same username and password as we would use to connect with a console. `# uid = no # Change to user name if you are running OpenVPN as a different user # than the console user. u = root@server.com # Password required`
