That means that for all points $x \in A$, $y \in B$ and a scalar α , one has that the "dot product" $\alpha(x+y)$ makes sense. Given the vector space A and the nonzero vector $x \in A$, the space A/x is indeed a space, in which we can make the quotient operation, and it is a vector space with respect to the usual scalar product. I am a little confused by the excerpt. Is it telling me that the abstract space, for all points $x \in A$ and a scalar α , we have that $\alpha(x+y)$ makes sense? That is, if one identifies the vector space with itself (in the same way we have that the vector space \mathbb{Z}_n can be identified with itself in the rational field \mathbb{Q} with the usual scalar product), then for all points $x \in A$ and a scalar α , $\alpha(x+y)$ makes sense? Why do we need to take the quotient of the first vector space to obtain the second vector space? A: We choose an additive $+$ and a scalar product on A so that we can make sense of the scalar product $\alpha(x+y)$ where x is some fixed vector of A and y is any vector of A . The vector space A is an arbitrary vector space and could be an n -dimensional vector space. The function $\alpha: \mathbb{K} \rightarrow A/x$ defined by $\alpha(x+y) = \alpha(x) \cdot \alpha(y)$ where x is a fixed vector and y is a vector in A .

Historical vii. | Academic libraries at a glance | Dc ontario government libraries and data centersCatalytic oxidation of methyl tert-butyl ether with different catalysts. Methyl tert-butyl ether (MTBE) is a common gasoline component. In gasoline, MTBE is used mainly as a gasoline oxygenate to enhance octane levels. Based on the differences in selectivity, productivity and cost between catalysts, in this work, four commercially-available catalysts were used to catalyze the oxidation of MTBE to tert-butanol (TBA) and carbon oxides (CO₂ and CO). The catalysts were HZSM-5, NH₂-HZSM-5, SAPO-11 and SAPO-14. After the initial step, the coke deposition was determined by the atomic absorption spectroscopy and potassium permanganate combustion methods. The results indicated that the activity of catalyst used in the second reaction was higher than that of the first reaction. This indicated that the catalyst had better selectivity for TBA. After the reaction, the CO₂ and CO concentrations were determined by a gas chromatograph. The coke deposition and the specific activity of the reaction mixture were increased when NH₂-HZSM-5 was used. The results suggest that NH₂-HZSM-5 has a better ability to maintain the catalytic activity during the reaction of MTBE to TBA.Q: How do we force a bijective function into a set of functions? For context, I'm just trying to fill the gaps in my knowledge of function theory. If I have a function $f: \mathbb{R} \rightarrow \mathbb{R}$ with $f(0) = 0$ and $f(x) = x^2$ for all $x \in \mathbb{R}$, how do we force f to be bijective?
