External sources may include lightning, radio and TV transmitters, transmissions from high-powered vehicles, and the like. Due to the varying levels and relative strength of the various external signals (which are a function of the channel usage), and the channel loading (i.e., the number of other signals present on a channel at the same time), the effect of such external signals and variations on the channel is to introduce a certain amount of distortion into the received signal. As is known in the art, a dynamic range of, for example, 28 dB is required to reliably remove even low level signals from a received signal. While this amount of signal quality degradation is quite tolerable for some purposes, it is not suitable for others. In fact, as the complexity of circuitry required to handle these signals increases, in order to provide high fidelity, high quality signal processing, distortion introduced by external signals increases.
